Day 05 ListIterator => It is used with only list

↳ it is specialized iterator that allows bidirectional traversal of List collection in Java

methods of List Iterator =>

(1) hasNext() -> return true/false -> used to check the existance of next element in the list

(2) hasPrevious() -> return true/false -> used to check the existance of previous element in the list

(3) next() -> return the next element and move the cursor forward

(4) previous() -> return the previous element and move the cursor backward.

These are known as navigation methods

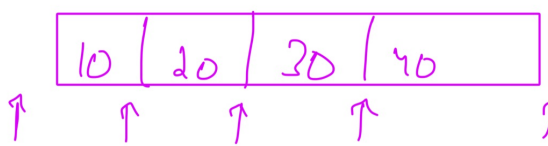

Index Methods

nextIndex() -> return the index of next object

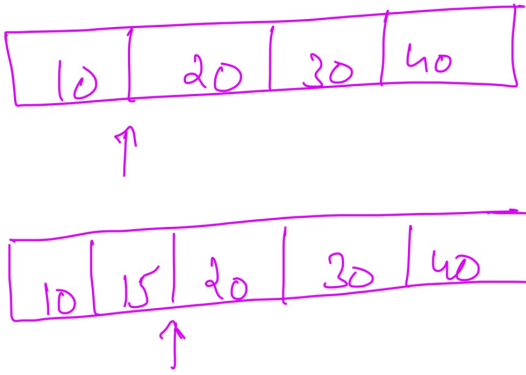

previousIndex() -> return the index of previous object

Modification method =>

(1) add(E e) =>

if we want to add 15 after 10

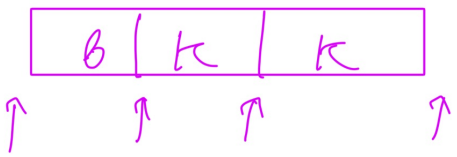

② set(Ee) → it is used to modify at particular index but this need only after next or previous

& cursor are not pointing to object

& in order to set we need to retrieve the object

② remove( ) → to remove object and only be used after retriving the object

add( ) example =>

```
if (str2.equals("k")) {
        itr2.add("Rupesh");
}
```
