Day 03 =>

Exception propagation =>

If exception is not handled in particular method then it is passed to its calling method till it is handled or program terminates

Ex =>

```
public class Demo {
    static void method2() {
        int a = 5, b = 0;
        System.out.println(a/b);
    }
    static void method1() {
        method2();
    }
    public static void main {
        method1();
    }
}
```

↓

It is example of unchecked Exception but it is implicitly

But if we want to throw explicitly then use throw and throws

Ex =>

```
public class Demo {

    static void method2() throws ArithmeticException {
        int a=5, b=0;
        if (b==0) {
            throw new ArithmeticException
            ("b cannot be zero");
        }
        System.out.println(a/b);
    }

    static void method1() {
        method2();
    }

    public static void main(String[] args) {
        method1();
    }
}
```

Note => In signature of methods we write throws which tells that method might throw an exception

Note => In case of uncheck exception it's not compulsory to write throws but

in case of checked exception it is mandatory to explicitly write throws in method signature.

(1) throw → to explicitly throw an exception in the code

(2) throws → used in a method signature to indicate which checked exception it might throw.
